

`core` app — Shared Foundations (no tables)

The bottom of the import pyramid. Foundation-purity is CI-enforced (gate [1/4]: core + accounts import NO domain app).

Purpose

Abstract building blocks every domain app inherits — nothing domain-specific.

Contents

Piece	What	Why
<code>TimeStampedModel</code>	abstract <code>created_at</code> / <code>updated_at</code> (<code>auto_now_add</code> / <code>auto_now</code>)	har row ka janm + last-touch time, ek hi jagah define
<code>ActiveManager</code>	<code>.active</code> manager (<code>is_active=True</code>)	soft-delete pattern: masters kabhi DELETE nahi hote, deactivate hote hain; default <code>.objects</code> un- touched so nothing hides accidentally
<code>observability.py</code>	logging helpers	shared infra

What tables: none (abstract = fields copied INTO each child's table).

Django Learning Notes

- **Abstract base models:** `class Meta: abstract=True` — inheritance copies columns into children; no JOIN, no extra table.
- **Non-default managers:** `.active` opt-in keeps queries explicit — 14 call-sites chose it deliberately (2026-05-29); a default override would have silently hidden rows everywhere.
- **Import-linter contract:** architecture as CI — the dependency direction is a TEST, not a convention.

Common mistake

Putting anything domain-flavored here. If it knows what an Adda is, it does not belong in core.
